This Model Policy* addresses coverage for Proton Beam Therapy.

**DESCRIPTION**
Proton Beam Therapy (PBT) is a technology for delivering conformal external beam radiation with positively charged atomic particles to a well-defined treatment volume. PBT is approved by the U.S. Food and Drug Administration.

Due to its unique dose deposition characteristics, PBT can, in certain situations, deliver the prescribed target dose while giving a lower dose to normal tissues as compared to photon-based forms of external beam radiotherapy.

Photon beams deposit their greatest amount of energy beneath the patient’s surface with a gradual reduction in energy deposition along the beam path as photons pass through the target and then through an exit point out of the body. In contrast, the physical profile of a beam of proton particles allows for the majority of its energy to be deposited over a very narrow range of tissue at a depth largely determined by the energy of the proton beam. A proton beam deposits relatively less radiation energy upon entering the body compared to a photon beam. The energy deposition of the proton beam then rapidly increases over a narrow range of tissue at a desired depth to produce an intense dose distribution pattern called the Bragg peak. Beyond the Bragg peak, energy and dose deposition rapidly decrease, resulting in the absence of any significant exit dose deposited in normal tissue beyond the target.

**TREATMENT**

**PBT Treatment Planning**
PBT can allow for radiation treatment plans that are highly conformal to the target volume. PBT planning defines the necessary field sizes, gantry angles and beam energies needed to achieve the desired radiation dose distribution.

An assessment of patient suitability for PBT is an important step in the process of care. Changes in the density and composition of tissues in the path of the beam have much greater impact on the delivered dose for protons than photons. Tissue interfaces, especially those with large differences in electron density, can lead to larger or unacceptable dosimetric uncertainties in PBT for certain patients.

PBT treatment planning is a multi-step process and shares functions common to other forms of external beam radiotherapy planning:

1. **Simulation and Imaging:** Three-dimensional image acquisition of the target region by simulation employing CT, CT/PET and/or MR scanning equipment is an essential prerequisite to PBT treatment planning. If respiratory or other normal organ motion is expected to produce significant movement of the target region during radiotherapy delivery, the radiation oncologist may additionally elect to order multi-phasic treatment planning image sets to account for motion when rendering target volumes. As in all forms of external beam...
radiation therapy, immobilization is critical. However, for PBT, the immobilization system can impact the dose distribution and therefore these devices must be carefully designed. Many photon-based patient immobilization devices are not appropriate for use in PBT.

2. **Contouring:** Defining the target and avoidance structures is a multi-step process:

   a. The radiation oncologist reviews the three-dimensional images and outlines the treatment target on each slice of the image set. The summation of these contours defines the Gross Tumor Volume (GTV). For multiple image sets, the physician may outline separate GTVs on each image set to account for the effect of normal organ motion upon target location and shape. Some patients may not have GTVs if they have had previous treatment with surgery or chemotherapy, in which case treatment planning will be based on CTVs as described below.

   b. The radiation oncologist draws a margin around the GTV to generate a Clinical Target Volume (CTV) which encompasses the areas at risk for microscopic disease (i.e., not visible on imaging studies). Other CTVs may be created based on the estimated volume of residual disease. For multiple image sets, the physician may draw this margin around an aggregate volume containing all image set GTVs to generate an organ-motion CTV, or Internal Target Volume (ITV).

   c. In X-ray therapy, to account for uncertainties in the planning and delivery processes, a final margin is then added to create a Planning Target Volume (PTV). Analogous to the approach used in X-ray therapy, a lateral target expansion guards against under-dosing the target in the presence of daily setup variation and/or organ and patient motion. With PBT, however, the target expansion in the beam direction must also ensure coverage for uncertainties in the range of the proton beam which may not perfectly match the radiologic depth of the target. The expansion in the beam direction may be different from the lateral expansion. Because the lateral and range expansions may differ for each beam, there is no longer a single PTV that is sufficient for a multi-field proton plan. Rather than prescribing a uniform dose to a PTV, in PBT the plan should be designed to cover the CTV in the presence of expected uncertainties.

   d. Nearby normal structures that could potentially be harmed by radiation (i.e., "organs at risk", or OARs) are also contoured.

3. **Radiation Dose Prescribing:** The radiation oncologist assigns specific dose coverage requirements for the CTV which will be met even in the presence of expected positional and range uncertainties. A typical prescription may define a dose that will be delivered to at least 99% of the CTV. This coverage requirement is often accompanied by a minimum acceptable point dose delivered within the CTV in the presence of expected uncertainties and a constraint describing an acceptable range of dose homogeneity. Additionally, PBT prescription requirements routinely include dose constraints for the OARs (e.g., upper limit of mean dose, maximum allowable point dose, and/or a critical volume of the OAR that must not receive a dose above a specified limit). Doses to normal structures must also be evaluated in the presence of delivery and range uncertainties. A treatment plan that satisfies these requirements and constraints should maximize the potential for disease control and minimize the risk of radiation injury to normal tissue.

4. **Dosimetric Planning and Calculations:** The qualified clinical medical physicist or a supervised dosimetrist calculates a treatment plan to deliver the prescribed radiation dose to the CTV and simultaneously satisfy the normal tissue dose constraints by delivering significantly lower doses to nearby organs. Delivery mechanisms vary, but through the use of scanning magnets or scattering devices PBT plans spread protons laterally over the extent of a target volume. In some cases, the lateral spread of the protons is controlled through the use of an aperture. Additionally, multiple proton energies are combined, through the use of mechanical absorbers or accelerator energy changes, to deliver the planned dose distribution over the longitudinal extent of the target. Range compensation devices are sometimes used to match the range of the proton beam to the distal edge of the
Regardless of the delivery technique, all delivery parameters and/or field specific hardware are developed by a medical physicist or supervised dosimetrist and an expected dose distribution is calculated for the treatment plan. While PBT plans may be more conformal than X-ray therapy plans, they may also be more susceptible to uncertainties in patient positioning or proton range in the patient. Nominal treatment plans should be evaluated in the presence of both positional and range uncertainties to ensure that the planned CTV coverage and normal tissue sparing are likely to be preserved under the range of expected uncertainties.

5. **Patient Specific Dose Verification:** An independent dose calculation and/or measurement should confirm that the intended dose distribution for the patient is physically verifiable and feasible.

Documentation of all aspects of the treatment planning process is essential.

**PBT Treatment Delivery**

Proton delivery methods can be described in one of two forms: scattering or scanning.

In scattered deliveries, the beam is broadened by scattering devices, beam energies are combined by mechanical absorbers and the beam is shaped by placing material such as collimators and compensators into the proton path.

In scanning deliveries, the beam is swept laterally over the target with magnets instead of with scattering devices. Collimators and range compensators are still sometimes used for lateral and distal beam shaping, but field specific hardware is not always required because the scanning magnets allow the lateral extent of the beam to be varied with each energy level, a technique sometimes called intensity-modulated proton therapy (IMPT).

The basic requirement for all forms of PBT treatment delivery is that the technology must accurately produce the calculated dose distribution described by the PBT plan. PBT dose distributions are sensitive to changes in target depth and shape and thus, changes in patient anatomy during treatment may require repeat planning. Such a change must be documented.

Precise delivery is vital for proper treatment. Therefore, imaging techniques such as stereoscopic X-ray or CT scan (collectively referred to as Image Guided Radiation Therapy or IGRT) should be utilized to verify accurate and consistent patient and target setup for every treatment fraction.

**Documentation Requirements**

Documentation in the patient medical record must:

1. Support one or more medical necessity requirement(s) as provided under the “Indications and Limitations of Coverage and/or Medical Necessity” section of this policy, if not enrolled on a clinical protocol or registry.

2. Include a treatment prescription that defines the goals of the treatment plan – including specific dose-volume parameters for the target and nearby critical structures – as well as pertinent details of beam delivery, such as method of beam modulation, field arrangement, and expected positional and range uncertainties.

3. Include a treatment plan, signed by a physician, which meets the prescribed dose-volume parameters for the clinical target volume (CTV) and surrounding organs at risk (OARs) in the presence of expected uncertainties.

4. Describe the target setup verification methodology, including patient positioning, immobilization and use of image guidance.

5. Include verification of planned dose distribution via independent dose calculation or physical measurement.
INDICATIONS AND LIMITATIONS OF COVERAGE AND/OR MEDICAL NECESSITY

Indications For Coverage

PBT is considered reasonable in instances where sparing the surrounding normal tissue cannot be adequately achieved with photon-based radiotherapy and is of added clinical benefit to the patient. Examples of such an advantage might be:

1. The target volume is in close proximity to one or more critical structures and a steep dose gradient outside the target must be achieved to avoid exceeding the tolerance dose to the critical structure(s).

2. A decrease in the amount of dose inhomogeneity in a large treatment volume is required to avoid an excessive dose “hotspot” within the treated volume to lessen the risk of excessive early or late normal tissue toxicity.

3. A photon-based technique would increase the probability of clinically meaningful normal tissue toxicity by exceeding an integral dose-based metric associated with toxicity.

4. The same or an immediately adjacent area has been previously irradiated, and the dose distribution within the patient must be sculpted to avoid exceeding the cumulative tolerance dose of nearby normal tissue.

PBT may offer dosimetric advantages as well as added complexity over conventional radiotherapy, 3D Conformal Radiation Therapy (3-D CRT) or Intensity Modulated Radiation Therapy (IMRT). Before applying PBT techniques, a comprehensive understanding of the benefits and consequences is required. In addition to satisfying at least one of the four selection criteria noted above, the radiation oncologist’s decision to employ PBT requires an informed assessment of the benefits and risks including:

- Determination of patient suitability for PBT allowing for reproducible treatment delivery.
- Adequate definition of the target volumes and OARs.
- Equipment capability, including ability to account for organ motion when relevant.
- Physician, physicist and staff training.
- Adequate quality assurance and safety procedures.

Coverage decision may extend beyond ICD-10 codes to incorporate additional considerations of clinical scenario and medical necessity with appropriate documentation, which in certain circumstances may include comparative dose volume histograms.

Group 1

On the basis of the above medical necessity requirements and published clinical data, disease sites that frequently support the use of PBT include the following:

- Ocular tumors, including intraocular melanomas
- Tumors that approach or are located at the base of skull, including but not limited to:
  - Chordoma
  - Chondrosarcomas
- Primary or metastatic tumors of the spine where the spinal cord tolerance may be exceeded with conventional treatment or where the spinal cord has previously been irradiated
- Hepatocellular cancer
- Primary or benign solid tumors in children treated with curative intent and occasional palliative treatment of childhood tumors when at least one of the four criteria noted above apply
- Patients with genetic syndromes making total volume of radiation minimization crucial such as but not limited to NF-1 patients and retinoblastoma patients
- Malignant and benign primary CNS tumors
- Advanced (eg, T4) and/or unresectable head and neck cancers
- Cancers of the paranasal sinuses and other accessory sinuses
- Non-metastatic retroperitoneal sarcomas
- Re-irradiation cases (where cumulative critical structure dose would exceed tolerance dose)

PBT is one of the acceptable forms of external beam radiation therapy that may be used to administer Stereotactic Body Radiation Therapy (SBRT) or Stereotactic Radiosurgery (SRS). Separate ASTRO Model Policies for SBRT\(^6\) and SRS\(^7\) include technology descriptions and a list of indications for which SBRT or SRS should be covered. When PBT is used to administer SBRT or SRS, the delivery and management codes relevant for SBRT or SRS apply, and the same clinical indications apply as for those treatment strategies.

**Group 2**

While PBT is not a new technology, there is a need for continued clinical evidence development and comparative effectiveness analyses for the appropriate use of PBT for various disease sites. All other indications not listed in Group 1 are suitable for Coverage with Evidence Development (CED). Radiation therapy for patients treated under the CED paradigm should be covered by the insurance carrier as long as the patient is enrolled in either an IRB-approved clinical trial or in a multi-institutional patient registry adhering to Medicare requirements for CED\(^2\). At this time, no indications are deemed inappropriate for CED and therefore Group 2 includes various systems such as, but not limited to, the following:

- Non-T4 and resectable head and neck cancers
- Thoracic malignancies, including non-metastatic primary lung and esophageal cancers, and mediastinal lymphomas
- Abdominal malignancies, including non-metastatic primary pancreatic, biliary and adrenal cancers
- Pelvic malignancies, including non-metastatic rectal, anal, bladder and cervical cancers
- Non-metastatic prostate cancer
- Breast cancer

In the treatment of prostate cancer, the use of PBT is evolving as the comparative efficacy evidence is still being developed. In order for an informed consensus on the role of PBT for prostate cancer to be reached, it is essential to collect further data, especially to understand how the effectiveness of proton therapy compares to other radiation therapy modalities such as IMRT and brachytherapy. There is a need for more well-designed registries and studies with sizable comparator cohorts to help accelerate data collection. Proton beam therapy for primary treatment of prostate cancer should only be performed within the context of a prospective clinical trial or registry\(^5\).

Coverage under CED requirements will help expedite more permanent coverage decisions for all indications. Due to the numerous studies under way, proton coverage policies need to be reviewed on a frequent basis. As additional clinical data is published, this policy will be revised to reflect appropriate coverage.

**ICD-9-CM and ICD-10-CM Codes that May be Associated with Medical Necessity**

Note: Diagnosis codes are based on the current ICD-10-CM codes that are effective at the time of the Model Policy publication. Any updates to ICD-10-CM codes will be reviewed by ASTRO, and coverage should not be presumed until the results of such review have been published/posted. These ICD diagnosis codes support medical necessity under this Model Policy.

ICD-10-CM T66.XXXA (Effects of Radiation, Unspecified) may only be used where prior radiation therapy to the site is the governing factor necessitating PBT in lieu of other radiotherapy. An ICD diagnosis code for the anatomic diagnosis must also be used with appropriate documentation.

**Group 2:**
The remaining ICD-10-CM (C00-D49) Neoplasm codes should be considered suitable for CED.

**Limitations of Coverage**
PBT is not considered reasonable and medically necessary unless at least one of the criteria listed in the “Indications of Coverage” section of this policy is present.

Use of PBT is not typically supported by the following clinical scenarios:

1. Where PBT does not offer an advantage over photon-based therapies that otherwise deliver good clinical outcomes and low toxicity.
2. Spinal cord compression, superior vena cava syndrome, malignant airway obstruction, poorly controlled malignant bleeding and other scenarios of clinical urgency.
3. Inability to accommodate for organ motion.
4. Palliative treatment in a clinical situation where normal tissue tolerance would not be exceeded in previously irradiated areas.
PHYSICIANS’ CURRENT PROCEDURAL TERMINOLOGY (CPT®)/HCPCS

Preparation for Treatment
Due to the complexity of this treatment technology and the cases commonly appropriate for it, all PBT cases satisfy the criteria for complex clinical treatment planning. The clinical treatment plan is the initial process in preparing the patient for treatment.

CPT® Code for Clinical Treatment Planning

77263 | Therapeutic Radiology Treatment Planning; complex
This code is typically reported only once per course of PBT.

Following clinical treatment planning and a decision to proceed with PBT, treatment simulation is performed. By definition, the simulation process is complex for protons since it involves particle therapy. CT guidance is now packaged into 77290 and is no longer separately billable.

CPT Code for Simulation

77290 | Therapeutic radiology simulation-aided field setting; complex
This code is typically reported only once per course of PBT.

+77293 | Respiratory motion management simulation (List separately in addition to code for primary procedure)
This is an add-on code and cannot be billed on its own. It should be billed with either CPT code 77295 or 77301.

The add-on code +77293 would be used in situations where respiratory motion may cause significant changes in target definition and localization for proton treatment delivery, most commonly in patients with lung or upper gastrointestinal malignancies.

Medical Radiation Physics, Dosimetry and Treatment Devices
In addition, when planning for any special beam such as particles (i.e. protons), a special teletherapy port plan may be necessary. The special teletherapy port plan must be reviewed, signed and dated by the radiation oncologist and physicist. The radiation oncologist must document involvement in the planning and selection of special beam parameters used for treatment.

CPT® Code for Special Teletherapy Port Plan

77321 | Special teletherapy port plan, particles, hemibody, total body
Use for particle beam isodose planning. Use for electrons, protons and neutron therapy; half body or total body therapy.

Isodose planning typically involves 3-dimensional dosimetry. For cases in which there is a need to optimize the dose distribution by modulating the beam energy and/or fluence across the field, an intensity modulated treatment plan may be indicated and should be reported using CPT 77301.

CPT Codes for Isodose Planning

77295 | Therapeutic radiology simulation-aided field setting; 3-dimensional
Use for particle beam isodose planning. Use for electrons, protons and neutron therapy; half body or total body therapy. This code has been moved to the medical physics and dosimetry section, since it represents the work of physics and dosimetry planning rather than the work performed in simulation.
### CPT Codes for Dosimetry

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>77300</td>
<td>Basic radiation dosimetry calculation; central axis depth, TDF, NSD, gap, off-axis factor, tissue inhomogeneity, calculation of non-ionizing radiation surface and depth dose, as required during course of treatment, only when prescribed by the treating physician.</td>
</tr>
</tbody>
</table>

*This code can generally be billed once for each beam or arc up to a limit of ten. This code is used to report dosimetry calculations that arrive at the relationship between monitor units (or time) and dose, and the physician’s verification, review, and approval. The documentation should contain the independent check of each field, separate from the computer-generated PBT plan.*

---

### CPT Codes for PBT Treatment Devices

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>77301</td>
<td>Intensity modulated radiotherapy plan, including dose-volume histograms for target and critical structure partial tolerance specifications.</td>
</tr>
</tbody>
</table>

*This code will typically be used for plans developed with pencil-beam scanning techniques. This code is typically reported only once per course of PBT.*

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>77307</td>
<td>Teletherapy isodose plan; complex (multiple treatment areas, tangential ports, wedges, blocking, rotational beam, or special beam considerations) includes basic dosimetry calculations.</td>
</tr>
</tbody>
</table>

After completion of isodose planning, an independent verification of the radiation dose should be performed by a medical dosimetrist, physicist or physician. A calculation is performed for each treatment field.

---

### CPT Codes for PBT Treatment Devices

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>77332</td>
<td>Treatment devices, design and construction; simple</td>
</tr>
</tbody>
</table>

*Simple treatment devices include simple multi-use shaped blocks, bolus and passive, multiuse devices.*

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>77333</td>
<td>Treatment devices, design and construction; intermediate</td>
</tr>
</tbody>
</table>

*Intermediate treatment devices include pre-cast or pre-made standard-shaped blocks, stents, and special bolus and bite blocks. For example, custom fabrication of a bolus to compensate for tissue defects; this would typically be done at the time of simulation.*

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>77334</td>
<td>Treatment devices, design and construction; complex</td>
</tr>
</tbody>
</table>

*Complex treatment devices include custom-fabricated cast blocks, immobilization devices, wedges, compensators and eye shields. This may include custom fabrication of immobilization devices during simulation (such as a vacuum-lock device or thermoplastic mask). A custom compensator designed to adjust the depth of penetration of the protons throughout the treatment volume and utilized for daily treatment, or an aperture (custom fabricated blocking device to design the shape of the proton beam), which would also be utilized for daily treatment. There may be an aperture and compensator designed and constructed for each treated field.*

Apertures or compensators (77334 – complex treatment devices) may be used in some circumstances with pencil-beam scanning. An example of this would be a compensator used to decrease the proton range for tumors in more superficial locations, such as in the brain. If the compensator used is a standard compensator which can be used for multiple patients, this would qualify as a simple treatment device (77332).
CPT Codes for Physics and Dosimetry Procedures

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>77331</td>
<td>Special dosimetry (eg, TLD, microdosimetry) (specify), only when prescribed by the treating physician. Explanation of medical necessity may be required.</td>
</tr>
<tr>
<td>77336</td>
<td>Continuing medical physics consultation, including assessment of treatment parameters, quality assurance of dose delivery, and review of patient treatment documentation in support of the radiation oncologist, reported per week of therapy. Reported per 5 fractions of therapy.</td>
</tr>
<tr>
<td>77370</td>
<td>Special medical radiation physics consultation. Radiation Oncologist makes a direct request to the qualified medical physicist for a special consultative report or for specific physics services for an individual patient.</td>
</tr>
</tbody>
</table>

Treatment Delivery

PBT delivery codes should be billed using one of the four following codes.

CPT® Codes for PBT Treatment Delivery

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>77520</td>
<td>Proton treatment delivery; simple, without compensation. Treatment to a single treatment area utilizing a single non-tangential/oblique port, custom block, without compensation.</td>
</tr>
<tr>
<td>77522</td>
<td>Proton treatment delivery; simple, with compensation. Treatment to a single treatment area utilizing a single non-tangential/oblique port, custom block, with compensation.</td>
</tr>
<tr>
<td>77523</td>
<td>Proton treatment delivery; intermediate. Treatment delivery to one or more treatment areas utilizing two or more ports or one or more tangential/oblique ports, with custom blocks and compensations.</td>
</tr>
<tr>
<td>77525</td>
<td>Proton treatment delivery; complex. Treatment delivery to one or more treatment areas utilizing two or more ports per treatment area with matching or patching fields and/or multiple isocenters, with custom blocks and compensators.</td>
</tr>
</tbody>
</table>

Compensation of the beams may be performed with specific physical compensating devices (custom fabricated lucite or wax compensators) or with compensation using electromagnetic alterations of the beam (pencil-beam scanning or spot scanning).
Image-Guided Radiation Therapy
Image Guided Radiation Therapy (IGRT) allows for modification of treatment delivery to increase precision. The following codes may be billed with PBT.

CPT® Codes for IGRT

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>77014</td>
<td>Computed tomography guidance for placement of radiation fields</td>
</tr>
<tr>
<td></td>
<td><em>Used with CT-based systems (i.e., integrated cone beam CT, CT/linear accelerator on rails, tomotherapy).</em></td>
</tr>
<tr>
<td>77387</td>
<td>Guidance for localization of target volume for delivery of radiation treatment delivery, includes intrafraction tracking, when performed</td>
</tr>
</tbody>
</table>

ADDITIONAL INFORMATION
Coding Guidelines
As a reminder, for Medicare claims, the HCPC/CPT® code(s) may be subject to Correct Coding Initiatives (CCI) edits. This policy does not take precedence over CCI edits. Please refer to the CCI for correct coding guidelines and specific applicable code combinations prior to billing Medicare.
